

Spring Boot

What is Spring boot ?

- The Spring framework all the modules like
 - Spring core
 - Spring Jdbc
 - Spring MVC

These all represent the functional aspect of programming or the way for building the application

Module	Functionality
- Spring Core	Dependency
- Spring Jdbc	DataBase Functionality
- Spring Mvc	Server based functionality

But spring boot doesn't represent any functional aspect it represent non functional aspect of building the application
spring boot came for making the spring framework modules which is representing the functional aspect by using them when we are creating the application spring boot help us to make the application effective and fast

with the functional aspect module of spring framework it are a lot issue are there
→ have

1. for activating the functionalities we should have to follow few rules

- we should have to write the configuration terms

- xml file

spring core

<list>

<set>

<map> <properties>

dependency injection
collection dependency
autowire

setter injecting

construction injection

field injection

<bean autowire=byName, byType

```
<bean>
<property>
<constructor-arg>
```

id ;

setNumber({})

- Spring Jdbc

JdbcTemplate

-DataSource

- DriverManagerDataSource

By working with configuration approach by writing inside the application-context.xml or any xml we are in that place where we have write a lot of logic for building our application

```
<bean id=jdbcTemplate class="">
<property name="DataSource" ref="DataSource">
```

```
<bean id=DataSource" class="DriverManagerDataSource">
```

```
<property drivername="">
```

```
<property url="">
```

```
<property username="">
```

```
<property password="">
```

```
<bean id="yourClass" class="your package">
<constructor-args ref="jdbcTemplate">
```

2. For these issues we are following the annotation approach for building the application faster by using spring module which follow some functional aspect

[- Stereotype Annotation	[- @Service , @Component , @RestController , @Controller , @Repository	
[spring core]		
[- @Autowired	[- @ComponentScan ()	[- @Bean
[- @DependsOn	[- @PropertiesSource	[- @Primary
[- @Lazy	[- @Qualifier	[- @Scope
[- @Values	[- @Configuration	
[persistence]		
[- @Entity	[- @Transient	[- @Data
[- @Table	[- @Id	[- @OneToMany
[- @Column	[- @Lob	[- @OneToOne , @ManyToOne , @ManyToMany
		[- @Embeddable

both
