

Spring Boot _Day01

What is Spring Boot ?

- Spring Boot is used for representing the non-functional aspect of the developing spring framework application

1st let's see what is functional aspect of programming

- For Dependency Management type of function we are using
 - Spring Core
- For Database application type of function we are using
 - Spring Jdbc
- For web application type of function we are using
 - Spring mvc

- Spring boot don't represent any of the functionality instead of it help the spring framework function aspect to the build the application much better

What is the issue if the application will build with spring functional aspect programming ?

- functional aspect programming provide by spring framework but the cost of getting the content is very large.
Think about it we have the spring core and spring Jdbc so when we writing the program we should have to write a lot of configuration file content to make the content active
For Example :
For activate the spring core dependency we should have write Application-context.xml
For activate the spring Jdbc dependecny we should have write the [application.properties](#) and the we should have write the configuration file
- The next issue is xml configuration approach we should have to write a lot lines of code as a result application development become little tough as a result annotation based approach introduced which help to resolve all the issue of configuration approach
- The next issue is annotation approach only we can use when we have the source code if the source code is not there with us then we cannot write the annoation for that the java configuration approach came into the picture
- The java configuration approach is again having the issue that a lot configuration file again we have to write as a result application development become slow.

Spring Boot

- Our class application component
[no java Configuratiob required]
- Framework component
[third - party api's like spring Jdbc]

In spring Jdbc we are using DriverManagerDataSource

DriverManagerDataSource

- driverClassName
- url
- username
- password

we are configuring the database terms as per our requirement again then we have to write the configuration file then what is the use of spring boot ?

But spring boot is telling that no need of writting the configuration for the third party api's like spring jdbc.

so the Question will come like then how automatically it will be configure

so when the user will add the spring jdbc dependency in the pom.xml as per the requirement to reach the functionality of database spring boot read the pom.xml and by default activate the h2 database by itself means if you don't provide the database by default spring boot provide the H2 database by itself but the development phase we are not using the h2 database which is temproray as a result we should go for the some exact database so the requirement is changes as a result just we have to provide the our database drivername , url , username and password in the propety files as a result the spring boot configure these in the application. without writting and java configuration or xml configuration whixh make the application faster

Spring boot defination

so we can say the spring boot is used to represent the non functional aspect of developing spring framework application , we can build the application faster manner as compare to functional aspect .
It also configures spring framework class or component over opiniated view (mean based on the provided requirement it will think) and if the requirement change or divert it will quickly change the terms with minimal changes and trouble.

So the 1st feature of spring boot is making the application faster by enable to auto feature for making the requirement changes better mean the developer have to not write the configuration by it's own so this thing represent by the feature known as "Auto configuration".
